One cycle, one component

The classifier emits $p_c(x)$, Eq. (1)

the explanations ask what that output
is sensitive to, one sensor group at a time

two attributions

Two views of the same fitted model

Local, per cycle

mean-impute the group,
re-query, take the drop, Eq. (3)

Global, per test set

permute the group,
take the AP drop, Eq. (4)

kept separate

What each view is used for

Occlusion

graph edges (Fig. 9) and
the $\bar{a}_c$ term of Eq. (5)

Permutation

Fig. 10(b) and the permutation-
weighted baseline only

one graph

What the graph does not claim

A model-sensitivity map

mean imputation queries the model off
the data manifold; edges are ordinal
evidence about the model, not physical
support or causal effect
