Three inputs, per component
Probability
$p_c(x)$ from the multi-output classifier
Explanation term
$\bar{a}_c(x)$, mean occlusion drop
Policy constants
S_c, E_c: illustrative, not elicited
one score per component
The score
$M_c = p_c(1 + \bar{a}_c)\, S_c/E_c$, Eq. (5)
kept simple so an operator can see which term produced an ordering
scored on held-out runs
The audit, leakage-safe blocked split
Probability only
top-1 error 0.022
Priority score
top-1 error 0.051
Static policies
top-1 error 0.265-0.330
reading the audit
What this benchmark settles
Reweighting reorders components
and raises top-1 error here; the priority weighting is a display convention until cost data exist to evaluate it
